ABSTRACT

BACKGROUND: Scapular dyskinesis is defined as visible alterations in scapular positions and motion patterns and is believed to occur as a result of changes in activation of scapular stabilizing muscles. Scapular dyskinesis is not associated with pain and appears to be prevalent in asymptomatic population. The strength deficits or muscular imbalance of scapular muscles lead to disoriented scapular movement, which may contribute to future shoulder injuries. So, this study aims to collect evidence regarding whether scapular dyskinesis is present in asymptomatic adults or not.

METHODS: A computer-based literature search was done using various database with keywords. In this review all types of studies were found. Based on predetermined selection criteria, present study included articles between 2012 to 2022, In which 8 out of 46 articles were fitted in the study on the basis of inclusion criteria.

RESULT: Results of all the studies reviewed, concluded that scapular dyskinesis is commonly seen in asymptomatic adults.

CONCLUSION: Strong evidence exists to show the presence of scapular dyskinesis in asymptomatic adults. Some study depicts the idea that asymptomatic individuals with scapular dyskinesis have strength deficits and require intervention to prevent future shoulder injuries.

Keywords: Scapular dyskinesis, Asymptomatic adults, Strength deficit, Scapular muscles imbalance

INTRODUCTION

The scapula is a key part of the upper limb kinematic chain and is a vital component of the glenohumeral rhythm.¹ The scapula is the base of support for all shoulder function and serves as the link in the kinetic chain between the upper extremity and the trunk. Proper scapular motion is essential to the performance of efficient and injury free overhead activities.² The scapula performs several functions contributing to stability and mobility of scapula complex.³ The scapular position in relation to the thorax is important because its abnormal position disrupts the normal bio-mechanics of the shoulder joint, leading to injury or abnormal posture.⁴ Optimal shoulder function requires proper positioning and movement of the scapula on the thorax.⁵ Altered scapular motion and position have been termed scapular dyskinesis. The definition of dyskinesis is the alteration of normal scapular kinematics. ‘Dys’ (alteration of) ‘kinesis’ (motion) is a general term that reflects the loss of normal control of scapular motion. Scapular Dyskinesis (SD) is defined as visible alterations in scapular positions & motion pattern and is believed to occur as a result of changes in activation of scapular stabilizing muscles.⁶
An abnormal position of the scapula is a sign of changes in the activity of surrounding muscles, and an abnormal movement of the scapula interferes with its coordinated movement with the humerus, resulting in loss of scapulohumeral rhythm and increased scapula damage. Dyskinesis can be identified by alterations in a single plane or across multiple planes. Alterations include: prominence of the inferior angle, medial border prominence (winging), and dysrhythmia. Prominence of the inferior angle is indicative of excessive anterior tipping of the scapular and may be a result of tightness/dominance of the pectoralis minor and weakness of the serratus anterior. Medial border prominence (winging), is indicative of excessive protraction of the scapula, and may be a result of tightness/dominance of the pectoralis minor or serratus anterior and weakness of the retractor muscles which include the middle trapezius and rhomboid muscle group.

Dysrhythmia indicates a more general lack of dynamic control of the scapula and is visible with early shrugging during humeral elevation and/or rapid downward rotation during humeral lowering. Causes of scapular dyskinesis include soft tissue mechanisms for scapular dyskinesis involve inflexibility (tightness) or intrinsic muscle problems. Inflexibility and stiffness of the pectoralis minor and biceps short head can create anterior tilt and protraction due to their pull on the coracoid. In addition, the upper trapezius/lower trapezius force couple may be altered, with delayed onset of activation in the lower trapezius, which alters scapular upward rotation and posterior tilt.

Dyskinesis by itself is not an injury or a musculoskeletal diagnosis. Dyskinesis has been hypothesized to relate to changes in GH angulation, AC joint strain, subacromial space dimension, shoulder muscle activation and humeral position and motion. Although it is typically associated with shoulder pain, dyskinesis also can be present in asymptomatic population. Scapular dyskinesis is also highly prevalent in the absence of shoulder pain. Scapular dyskinesis is also associated with abnormal posture and muscle tightness. Many authors have suggested that forward head posture and increased thoracic kyphosis may contribute to scapular protraction and lead to adaptive shortening of postural muscles or muscular strength imbalances.

More recent evidence suggests that scapular dyskinesis is a risk factor for shoulder pain that may warrant screening as a preventative measure. Scapula dyskinesis should be evaluated and treated, as part of normal shoulder rehabilitation programme, because the untreated condition may exacerbate shoulder symptoms - or adversely affect treatment outcomes. So, the purpose of the study is to review the literature regarding presence of scapular dyskinesis in asymptomatic adults.

**Aim Of The Study**
Study aims to review available literature to determine whether scapular dyskinesis is present or not in asymptomatic adults.

**Objectives Of The Study**
All the available literatures were reviewed to determine whether scapular dyskinesis is present or not in asymptomatic adults.

**MATERIALS & METHODS**
A computer-based literature search was conducted using the Google Scholar, PubMed, PubMed Central, and ResearchGate, Cochrane from 2012 to 2022. Different combinations of the terms like Scapular dyskinesis, asymptomatic adults, strength, scapular muscle imbalance, posture, hand dominance were used for searching.

- Research Design: A Narrative Review
- Population: Scapular Dyskinesis
- Inclusion Criteria
  - Article published from 2012 to 2022
• Observational study, Case study, Cross-Sectional study, Reliability Study
• Only full text articles are included.

➢ Exclusion Criteria
• Systemic Review and Meta- Analysis
• Interventional Studies

- Any study conducted prior to 2012
- The search was limited to journals published in English, 170 articles were obtained from the search out of which 124 were excluded directly on the basis of exclusion criteria, 38 excluded as the aim of the review did not match. Remaining 8 articles were reviewed.

**Keywords used for searching strategies**

Total articles searched from various data base (n=170)

Articles excluded on the basis of

Full text articles screened on the basis of inclusion criteria (n=46)

Articles not matched with the

Studies included (n=8)

**RESULT**

Altogether, 170 records were identified from the selected databases. 124 studies were excluded on the basis of exclusion criteria. Forty-six full text articles were screened on the basis of inclusion criteria. Out of which thirty-eight studies were not matched with the aim of the study. Finally, 8 studies were included in this review for the qualitative synthesis.

**DISCUSSION**

The scapula is a link between the trunk and arm, and is part of the kinetic chain. Deficits in the kinetic chain, such as inadequate muscle strength and improper muscle activation can lead to impaired function and injury. The result of the reviewed studies found that there is decrease in strength of the trunk flexors and hip extensors, and periscapular muscles in asymptomatic adults with Scapular dyskinesis. anterior tilt and protraction of the scapula as a result of their pull on the coracoid.20 Uhl TL et al. did study on evaluation of clinical assessment methods for scapular dyskinesis, in their study authors found that that asymmetries are common in symptomatic and asymptomatic populations.21

Recent prospective studies have showed that individuals with scapular dyskinesis may present with higher risk of developing shoulder pain than those without dyskinesis. Scapular dyskinesis appears to be prevalent in asymptomatic populations. Scapular dyskinesis is not associated with pain and does not alter measures of shoulder function in amateur adolescent. It is increasingly apparent that scapular dyskinesis exists in asymptomatic populations as well.22 Scapular dyskinesis is also prevalent in gymers as well as in non gymers. Due to lack of strengthening of the scapular stabilizers and over strengthening of shoulder abductors in the gym leads to instability of scapular stabilizers to work efficiently and hence leading to presence of scapular dyskinesis.

Other studies done in asymptomatic adults with Scapular dyskinesis found that hand dominance may also have an impact on Scapular dyskinesis. The effects of dominant side as increased upward rotation, internal rotation, and anterior tilt at higher humero-thoracic angles for all plane of arm motion. Also, some studies shows that Postural variations such as forward head and rounded shoulder can also alter the scapular position which can lead to Scapular dyskinesis in young adults. A shortened pectoralis minor has been suggested to be a contributing cause of symptoms in patients with impingement, but has been shown to

alter three-dimensional scapular kinematics in healthy subjects only. This tight muscle creates a position of scapular protraction at rest and may limit scapular posterior tilt or external rotation upon arm motion, potentially predisposing patients to impingement symptoms. Many authors have suggested that forward head posture and increased thoracic kyphosis may contribute to scapular protraction and lead to adaptive shortening of postural muscles or muscular strength imbalances. A protracted scapular position may be associated with a narrowed subacromial space, upright posture with increased subacromial space and a flexed thoracic spine and forward shoulder position alters scapular motion and results in diminished force output with elevation.

Many people, including students, find it difficult to maintain the proper and correct sitting posture for long hours during the day (because of fatigue in the lumbar extensor muscles). Hence, most of them use the comfortable sitting or reclining position. Becoming accustomed to the reclining position can cause Rounded shoulder posture (RSP) deviation in those individuals. According to the studies, this postural deviation can impact scapular kinematics. Considering the larger incidence of scapular dyskinesis in individuals with RSP, it is recommended that in preventive and rehabilitation programs for persons with RSP, muscle strengthening, which is useful in scapula stability and movement, should be considered.

CONCLUSION
This narrative review explains the presence of scapular dyskinesis in asymptomatic adults. Posture and other factors that are found to affect normal scapular position can lead to Scapular dyskinesis in asymptomatic individuals.

Some study depicts the idea that asymptomatic individuals with scapular dyskinesis have strength deficits and require intervention to prevent future shoulder injuries.
